1. Bitcoin. Cryptocurrencies. So hot right now.

Since the <u>launch of Bitcoin in 2008 (https://newfronttest.bitcoin.com/bitcoin.pdf)</u>, hundreds of similar projects based on the blockchain technology have emerged. We call these cryptocurrencies (also coins or cryptos in the Internet slang). Some are extremely valuable nowadays, and others may have the potential to become extremely valuable in the future¹. In fact, the 6th of December of 2017 Bitcoin has a <u>market capitalization (https://en.wikipedia.org/wiki/Market_capitalization)</u> above \$200 billion.

The astonishing increase of Bitcoin market capitalization in 2017.

*1- **WARNING**: The cryptocurrency market is exceptionally volatile and any money you put in might disappear into thin air. Cryptocurrencies mentioned here **might be scams** similar to <u>Ponzi Schemes</u> (https://en.wikipedia.org/wiki/Ponzi_scheme) or have many other issues (overvaluation, technical, etc.). **Please do not mistake this for investment advice.** *

That said, let's get to business. As a first task, we will load the current data from the <u>coinmarketcap API</u> (https://api.coinmarketcap.com) and display it in the output.

2. Full dataset, filtering, and reproducibility

The previous API call returns only the first 100 coins, and we want to explore as many coins as possible. Moreover, we can't produce reproducible analysis with live online data. To solve these problems, we will load a CSV we conveniently saved on the 6th of December of 2017 using the API call https://api.coinmarketcap.com/v1/ticker/?limit=0 named datasets/coinmarketcap_06122017.csv.

3. Discard the cryptocurrencies without a market capitalization

Why do the count() for id and market_cap_usd differ above? It is because some cryptocurrencies listed in coinmarketcap.com have no known market capitalization, this is represented by NaN in the data, and NaNs are not counted by count(). These cryptocurrencies are of little interest to us in this analysis, so they are safe to remove.

4. How big is Bitcoin compared with the rest of the cryptocurrencies?

At the time of writing, Bitcoin is under serious competition from other projects, but it is still dominant in market capitalization. Let's plot the market capitalization for the top 10 coins as a barplot to better visualize this

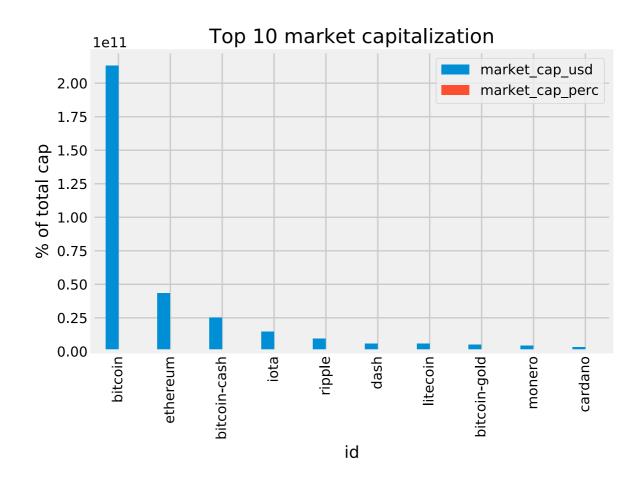

```
In [5]: #Declaring these now for later use in the plots
    TOP_CAP_TITLE = 'Top 10 market capitalization'
    TOP_CAP_YLABEL = '% of total cap'

# Selecting the first 10 rows and setting the index
    cap10 = cap.iloc[:10].set_index('id')

# Calculating market_cap_perc
    cap10 = cap10.assign(market_cap_perc = lambda x: (x.market_cap_usd / cap.market_cap_usd.sum())*100)

# Plotting the barplot with the title defined above
    ax = cap10.plot.bar()

# Annotating the y axis with the label defined above
    plt.title(TOP_CAP_TITLE)
    plt.ylabel(TOP_CAP_YLABEL)
    plt.show()
```

5. Making the plot easier to read and more informative

While the plot above is informative enough, it can be improved. Bitcoin is too big, and the other coins are hard to distinguish because of this. Instead of the percentage, let's use a \log^{10} scale of the "raw" capitalization. Plus, let's use color to group similar coins and make the plot more informative¹.

For the colors rationale: bitcoin-cash and bitcoin-gold are forks of the bitcoin <u>blockchain</u> (https://en.wikipedia.org/wiki/Blockchain)2. Ethereum and Cardano both offer Turing Complete smart contracts (https://en.wikipedia.org/wiki/Smart contract). Iota and Ripple are not minable. Dash, Litecoin, and Monero get their own color.

¹ This coloring is a simplification. There are more differences and similarities that are not being represented here.

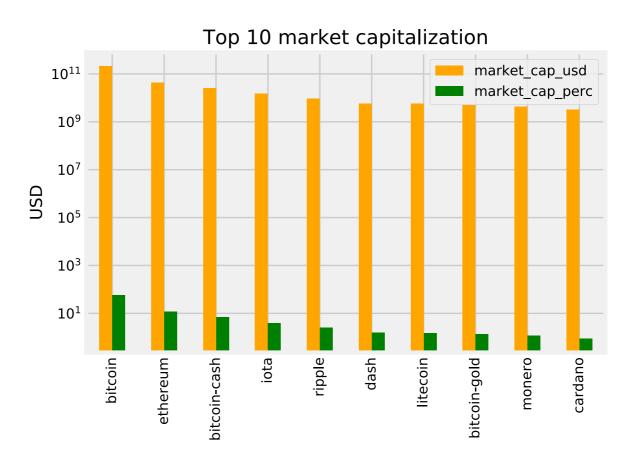

² The bitcoin forks are actually **very** different, but it is out of scope to talk about them here. Please see the warning above and do your own research.

```
In [6]: # Colors for the bar plot
    COLORS = ['orange', 'green', 'orange', 'cyan', 'cyan', 'blue', 'sil
    ver', 'orange', 'red', 'green']

# Plotting market_cap_usd as before but adding the colors and scali
    ng the y-axis
    ax = cap10.plot.bar(color=COLORS)
    ax.set_yscale('log')
    plt.title('Top 10 market capitalization')
# Annotating the y axis with 'USD'
    plt.ylabel('USD')

# Final touch! Removing the xlabel as it is not very informative
    plt.xlabel('')
```

Out[6]: Text(0.5, 0, '')

6. What is going on?! Volatility in cryptocurrencies

The cryptocurrencies market has been spectacularly volatile since the first exchange opened. This notebook didn't start with a big, bold warning for nothing. Let's explore this volatility a bit more! We will begin by selecting and plotting the 24 hours and 7 days percentage change, which we already have available.

```
In [7]: # Selecting the id, percent_change_24h and percent_change_7d column
s
volatility = dec6.loc[:,['id','percent_change_24h', 'percent_change
_7d']]

# Setting the index to 'id' and dropping all NaN rows
volatility = volatility.dropna().set_index('id')

# Sorting the DataFrame by percent_change_24h in ascending order
volatility = volatility.sort_values(by=['percent_change_24h'])

# Checking the first few rows
print(volatility.head())
```

	percent_change_24h	percent_change_7d
id		
flappycoin	-95.85	-96.61
credence-coin	-94.22	-95.31
coupecoin	-93.93	-61.24
tyrocoin	-79.02	-87.43
petrodollar	-76.55	542.96

7. Well, we can already see that things are a bit crazy

It seems you can lose a lot of money quickly on cryptocurrencies. Let's plot the top 10 biggest gainers and top 10 losers in market capitalization.

```
In [8]: #Defining a function with 2 parameters, the series to plot and the
        title
        def top10_subplot(volatility_series, title):
            # Making the subplot and the figure for two side by side plots
            fig, axes = plt.subplots(nrows=1, ncols=2, figsize=(10, 6))
            # Plotting with pandas the barchart for the top 10 losers
            ax = (volatility series[:10].plot.bar(ax=axes[0], color='darkre
        d'))
            # Setting the figure's main title to the text passed as paramet
        er
            fig.suptitle(title)
            # Setting the ylabel to '% change'
            ax.set_ylabel('% change')
            # Same as above, but for the top 10 winners
            ax = (volatility series[-10:].plot.bar(ax=axes[1], color='darkb
        lue'))
            # Returning this for good practice, might use later
            return fig, ax
        DTITLE = "24 hours top losers and winners"
        # Calling the function above with the 24 hours period series and ti
        tle DTITLE
        fig, ax = top10_subplot(volatility.percent_change_24h, DTITLE)
```

8. Ok, those are... interesting. Let's check the weekly Series too.

800% daily increase?! Why are we doing this tutorial and not buying random coins?¹

After calming down, let's reuse the function defined above to see what is going weekly instead of daily.

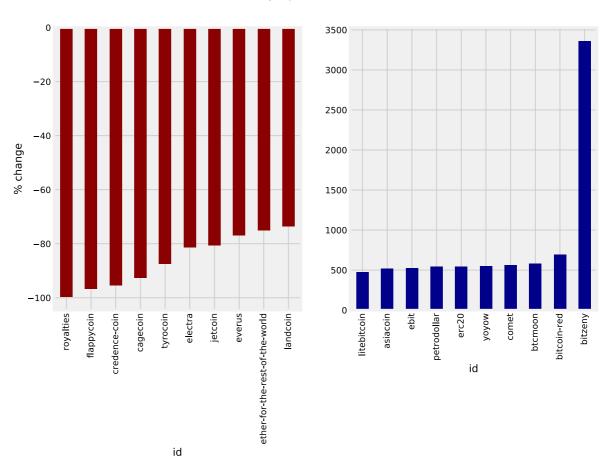

¹ Please take a moment to understand the implications of the red plots on how much value some cryptocurrencies lose in such short periods of time

In [9]: # Sorting in ascending order
volatility7d = volatility.sort_values(by='percent_change_7d', ascen
ding=True)

WTITLE = "Weekly top losers and winners"

Calling the top10_subplot function
fig, ax = top10_subplot(volatility7d.percent_change_7d, WTITLE)

Weekly top losers and winners

9. How small is small?

The names of the cryptocurrencies above are quite unknown, and there is a considerable fluctuation between the 1 and 7 days percentage changes. As with stocks, and many other financial products, the smaller the capitalization, the bigger the risk and reward. Smaller cryptocurrencies are less stable projects in general, and therefore even riskier investments than the bigger ones¹. Let's classify our dataset based on Investopedia's capitalization <u>definitions</u> (https://www.investopedia.com/video/play/large-cap/) for company stocks.

¹ Cryptocurrencies are a new asset class, so they are not directly comparable to stocks. Furthermore, there are no limits set in stone for what a "small" or "large" stock is. Finally, some investors argue that bitcoin is similar to gold, this would make them more comparable to a <u>commodity</u> (https://www.investopedia.com/terms/c/commodity.asp) instead.

10. Most coins are tiny

Note that many coins are not comparable to large companies in market cap, so let's divert from the original Investopedia definition by merging categories.

This is all for now. Thanks for completing this project!

```
In [12]: # Making a nice function for counting different marketcaps from the
         # "cap" DataFrame. Returns an int.
         # INSTRUCTORS NOTE: Since you made it to the end, consider it a gif
         def capcount(query_string):
             return cap.query(query string).count().id
         # Labels for the plot
         LABELS = ["biggish", "micro", "nano"]
         # Using capcount count the biggish cryptos
         biggish = capcount('market cap usd > 300000000')
         # Same as above for micro ...
         micro = capcount('market cap usd > 50000000 and market cap usd < 30
         0000000')
         # ... and for nano
         nano = capcount('market cap usd < 50000000')</pre>
         # Making a list with the 3 counts
         values = [biggish, micro, nano]
         # Plotting them with matplotlib
         plt.bar(range(len(values)), values, tick label=LABELS)
         plt.show()
```
